

Name: Davonn Escobilla	Date Performed: 28/10/2022
Course/Section: CPE31S24	Date Submitted: 28/10/2022
Instructor: Dr. Jonathan Taylar	Semester and SY: 1st sem, 2022-2023
Activity 10: Install, Configure, and Manage Log Monitoring tools	
1. Objectives	
Create and design a workflow that installs, configure and manage enterprise log monitoring tools using Ansible as an Infrastructure as Code (IaC) tool.	
2. Discussion	
<p>Log monitoring software scans and monitors log files generated by servers, applications, and networks. By detecting and alerting users to patterns in these log files, log monitoring software helps solve performance and security issues. System administrators use log monitoring software to detect common important events indicated by log files.</p> <p>Log monitoring software helps maintain IT infrastructure performance and pinpoints issues to prevent downtime and mitigate risks. These tools will often integrate with IT alerting software, log analysis software, and other IT issue resolution products to more aptly flesh out the IT infrastructure maintenance ecosystem.</p> <p>To qualify for inclusion in the Log Monitoring category, a product must:</p> <ul style="list-style-type: none"> • Monitor the log files generated by servers, applications, or networks • Alert users when important events are detected • Provide reporting capabilities for log files <p>Elastic Stack</p> <p>ELK suite stands for Elasticsearch, Kibana, Beats, and Logstash (also known as the ELK Stack). Source: https://www.elastic.co/elastic-stack</p> <p>The Elastic Stack is a group of open source products from Elastic designed to help users take data from any type of source and in any format, and search, analyze and visualize that data in real time. The product group was formerly known as the ELK Stack for the core products in the group -- Elasticsearch, Logstash and Kibana -- but has been rebranded as the Elastic Stack. A fourth product, Beats, was subsequently added to the stack. The Elastic Stack can be deployed on premises or made available as software as a service (SaaS). Elasticsearch supports Amazon Web Services (AWS), Google Cloud Platform and Microsoft Azure.</p>	

GrayLog

Graylog is a powerful platform that allows for easy log management of both structured and unstructured data along with debugging applications.

It is based on Elasticsearch, MongoDB, and Scala. Graylog has a main server, which receives data from its clients installed on different servers, and a web interface, which visualizes the data and allows to work with logs aggregated by the main server.

We use Graylog primarily as the stash for the logs of the web applications we build. However, it is also effective when working with raw strings (i.e. syslog): the tool parses it into the structured data we need. It also allows advanced custom search in the logs using structured queries. In other words, when integrated properly with a web app, Graylog helps engineers to analyze the system behavior on almost per code line basis.

Source: <https://www.graylog.org/products/open-source>

3. Tasks

1. Create a playbook that:
 - a. Install and configure Elastic Stack in separate hosts (Elastic Search, Kibana, Logstash)
2. Apply the concept of creating roles.
3. Describe how you did step 1. (Provide screenshots and explanations in your report. Make your report detailed such that it will look like a manual.)
4. Show an output of the installed Elastic Stack for both Ubuntu and CentOS.
5. Make sure to create a new repository in GitHub for this activity.

4. Output (screenshots and explanations)

First step is to create a repository for Activity 10.

Create a new repository

A repository contains all project files, including the revision history. Already have a project repository elsewhere?

[Import a repository.](#)

Owner *

DavonnEscobilla ▾

Repository name *

Escobilla_Act10 ✓

Great repository names are short and memorable. Need inspiration? How about **super-duper-computing-machine?**

Description (optional)

Public

Anyone on the internet can see this repository. You choose who can commit.

Private

You choose who can see and commit to this repository.

Initialize this repository with:

Skip this step if you're importing an existing repository.

Add a README file

This is where you can write a long description for your project. [Learn more.](#)

Second step, clone the repository to the managed node.

```
davonn@workstation:~$ git clone git@github.com:DavonnEscobilla/Escobilla_Act10.git
Cloning into 'Escobilla_Act10'...
warning: You appear to have cloned an empty repository.
davonn@workstation:~$ ls
CPE232_Davonn  Downloads  Music      Templates
CPE232_Escobilla  Escobilla_Act10  nano.save  Videos
Desktop        Escobilla_Act8Nagios  Pictures
Documents      Escobilla_Act9Prometheus  Public
```

Third step, create ansible.cfg and inventory file for control nodes.

```
davonn@workstation: ~/Escobilla_Act10
GNU nano 4.8 ansible.cfg
[defaults]
inventory = inventory
private_key_file = ~/.ssh/ansible
```

```
davonn@workstation: ~/Escobilla_Act10
GNU nano 4.8 inventory
[CentOS]
192.168.56.105

[Ubuntu]
192.168.56.103
```

Before proceeding to the next step, check the connectivity of the managed node to the control node.

```
davonn@workstation: ~/Escobilla_Act10
davonn@workstation:~/Escobilla_Act10$ ansible -m ping all
192.168.56.105 | SUCCESS => {
  "ansible_facts": {
    "discovered_interpreter_python": "/usr/bin/python"
  },
  "changed": false,
  "ping": "pong"
}
192.168.56.103 | SUCCESS => {
  "ansible_facts": {
    "discovered_interpreter_python": "/usr/bin/python3"
  },
  "changed": false,
  "ping": "pong"
}
```

Fourth step, create the `elk.yml` and configure the tasks.

davonn@workstation: ~/Escobilla_Act10

GNU nano 4.8

elsk.yml

```
---  
  
- hosts: all  
  become: true  
  pre_tasks:  
  
    - name: Update repository index (Ubuntu)  
      tags: always  
      apt:  
        update_cache: yes  
        changed_when: false  
        when: ansible_distribution == "Ubuntu"  
  
    - name: Update repository index (CentOS)  
      tags: always  
      yum:  
        update_cache: yes  
        changed_when: false  
        when: ansible_distribution == "CentOS"  
  
    - name: Install httpd on CentOS  
      tags: centos, apache, httpd  
      service:  
        name: httpd  
        state: started
```

```
davonn@workstation: ~/Escobilla_Act10
GNU nano 4.8                                elsk.yml

- name: Update repository index (CentOS)
  tags: always
  yum:
    update_cache: yes
    changed_when: false
    when: ansible_distribution == "CentOS"

- name: Install httpd on CentOS
  tags: centos, apache, httpd
  service:
    name: httpd
    state: started
    when: ansible_distribution == "CentOS"

- hosts: centos
  become: true
  roles:
    - centos

- hosts: ubuntu
  become: true
  roles:
    - ubuntu
```

Fifth step is to create a role and directory for Ubuntu and CentOS. Under each directory create a main.yml that contains tasks to be executed.

```
davonn@workstation:~/Escobilla_Act10$ mkdir roles
davonn@workstation:~/Escobilla_Act10$ cd roles
davonn@workstation:~/Escobilla_Act10/roles$ mkdir ubuntu
davonn@workstation:~/Escobilla_Act10/roles$ cd ubuntu
davonn@workstation:~/Escobilla_Act10/roles/ubuntu$ mkdir tasks
davonn@workstation:~/Escobilla_Act10/roles/ubuntu$ cd tasks
davonn@workstation:~/Escobilla_Act10/roles/ubuntu/tasks$ nano main.yml
```

davonn@workstation: ~/Escobilla_Act10/roles/ubuntu/tasks

GNU nano 4.8

main.yml

```
- name: Install Elastic Dependencies (Ubuntu)
  apt:
    name:
      - openjdk-11-jdk
      - apt-transport-https
      - curl
      - gpgv
      - gpgsm
      - gnupg-l10n
      - gnupg
      - dirmngr
    state: latest

- name: Get PGP Key (Ubuntu)
  apt_key:
    url: https://artifacts.elastic.co/GPG-KEY-elasticsearch
    state: present

- name: Install Elasticsearch sources list (Ubuntu)
  apt_repository:
    repo: deb https://artifacts.elastic.co/packages/7.x/apt stable main

  file:
    path: "/etc/systemd/system/elasticsearch.service.d"
    state: directory

- name: Creating an empty file for startup-timeout.conf 2 of 2 (Ubuntu)
  file:
    path: "/etc/systemd/system/elasticsearch.service.d/startup-timeout.conf"
    state: touch

- name: Prevent systemd service start operation from timing out (Ubuntu)
  copy:
    dest: "/etc/systemd/system/elasticsearch.service.d/startup-timeout.conf"
    content: |
      [Service]
      TimeoutStartSec=3min
```

davonn@workstation: ~/Escobilla_Act10/roles/ubuntu/tasks

GNU nano 4.8

main.yml

- name: Run daemon-reload for elasticsearch (Ubuntu)
systemd: daemon_reload=yes
- name: Enable service Elasticsearch and ensure it is not masked (Ubuntu)
systemd:
 - name: elasticsearch
 - enabled: yes
 - masked: no
- name: ensure elasticsearch is running (Ubuntu)
systemd: state=started name=elasticsearch
- name: Install Logstash (Ubuntu)
apt:
 - name: logstash
 - state: latest
 - update_cache: yes
- name: Run daemon-reload for logstash (Ubuntu)
systemd: daemon_reload=yes
- name: Enable service logstash (Ubuntu)
systemd:
 - name: logstash
 - enabled: yes

davonn@workstation: ~/Escobilla_Act10/roles/ubuntu/tasks

GNU nano 4.8

main.yml

```
- name: ensure logstash is running (Ubuntu)
  systemd: state=started name=logstash

- name: Install Kibana (Ubuntu)
  apt:
    name: kibana
    state: latest
    update_cache: yes

- name: Configure Kibana Add server.port (Ubuntu)
  lineinfile:
    dest: /etc/kibana/kibana.yml
    line: "server.port: 5601"
    state: present

- name: Configure Kibana Add server.host (Ubuntu)
  lineinfile:
    dest: /etc/kibana/kibana.yml
    line: 'server.host: "0.0.0.0"'
    state: present

- name: Configure Kibana Add server.name (Ubuntu)
  lineinfile:
    dest: /etc/kibana/kibana.yml
```

```
davonn@workstation: ~/Escobilla_Act10/roles/ubuntu/tasks
GNU nano 4.8 main.yml
lineinfile:
  dest: /etc/kibana/kibana.yml
  line: 'server.name: "demo-kibana"'
  state: present

- name: Configure Kibana Add elasticsearch.hosts (Ubuntu)
  lineinfile:
    dest: /etc/kibana/kibana.yml
    line: 'elasticsearch.hosts: ["http://0.0.0.0:9200"]'
    state: present

- name: Run daemon-reload for kibana (Ubuntu)
  systemd: daemon_reload=yes

- name: Enable service Kibana (Ubuntu)
  systemd:
    name: kibana
    enabled: yes

- name: Start Elasticsearch service
  shell: systemctl start elasticsearch

- name: Start Kibana
  shell: systemctl start kibana
```

After creating main.yml for Ubuntu, create another for CentOS.

```
davonn@workstation:~/Escobilla_Act10/roles$ ls
centos  ubuntu
davonn@workstation:~/Escobilla_Act10/roles$ cd centos
davonn@workstation:~/Escobilla_Act10/roles/centos$ mkdir tasks
davonn@workstation:~/Escobilla_Act10/roles/centos$ cd tasks
davonn@workstation:~/Escobilla_Act10/roles/centos/tasks$ nano main.yml
```

davonn@workstation: ~/Escobilla_Act10/roles/centos/tasks

skipped=1    rescued=0    ignored=0
```

The playbook ran smoothly and successfully executed all the tasks without error. The last procedure is to check all the installed programs on control nodes.

Reflections:

Answer the following:

1. What are the benefits of having a log monitoring tool?

Having a log monitoring tool saves time to access the scanned and log files from the servers, application, and networks. It can be used to inform the users about

the log files. It can be also used to properly handle security problems and performance issues. Upon detecting the problems, it can mitigate the downtime and risks.

Conclusions:

Upon performing the activity, I have difficulties finding references to properly handle the tasks implemented on each server. The playbook became very long since there are a lot of tasks that need to be implemented. Also, the installation on the control nodes takes a lot of time to finish since my computer is not that strong. Even so, I have managed to properly perform the activity and get the desired output.
